Wind turbine basics: the pitch hub

Pitch Hub

Housed in the hub that supports the blades, the pitch system is a combination of components that monitor and manipulate blade angles to control rotation speed, as well as the area exposed to the wind.

Pitch hub learning systems

There are two main technologies used to control pitch hubs: electricity and hydraulics.
This is why we offer two types of pitch hubs learning systems:

Electrical Pitch Hub –
Wind Turbine Learning System

Hydraulic Pitch Hub –
Wind Turbine Learning System

Electrical/Hydraulic Pitch Hubs: common characteristics

- Fully-operational learning systems
- Include all the components of a typical commercial hub
- Address blade pitch control and emergency back-up systems using the electrical or hydraulic technologies for pitch control
- The wind is simulated and the system reacts according to a commercial turbine typical behavior

... they are a perfect complement to the Nacelle – Wind Turbine Learning System.

Electrical/Hydraulic Pitch Hubs: common characteristics

- System feature a blade controlled by a PLC, in a scale down design similar to an actual wind turbine blade pitch control system
- UPS inside the electric panel to simulate power failure behavior
- Siemens HMI connected to a PLC
- Faults can be triggered through the HMI

Electrical Pitch Hub: specific characteristics

Teach electrical control of blade pitch angle

- Servomotor actuation of the blade movement
- Over travel limit switches
- Blade representation inside the slewing ring
- For safety purposes, the representative rotor blade is enclosed behind a clear plastic panel that cannot be opened.
